**Screening for Depression During and After Pregnancy**

**ABSTRACT:** Depression is very common during pregnancy and the postpartum period. At this time, there is insufficient evidence to support a firm recommendation for universal antepartum or postpartum screening. There are also insufficient data to recommend how often screening should be done. There are multiple depression screening tools available for use.

Clinical depression is common in reproductive-aged women (1). A recent retrospective cohort analysis in a large U.S. managed care organization found that one in seven women was treated for depression between the year prior to pregnancy and the year after pregnancy (2). According to the World Health Organization, depression is the leading cause of disability in women, which accounts for $30 billion to $50 billion in lost productivity and direct medical costs in the United States each year (3).

Screening for, diagnosing, and treating depression have the potential to benefit a woman and her family. Infants of depressed mothers display delayed psychologic, cognitive, neurologic, and motor development (3). Furthermore, children’s mental and behavioral disorders improve when maternal depression is in remission (4). Women with current depression or a history of major depression warrant particularly close monitoring and evaluation. Pregnancy and the postpartum period represent an ideal time during which consistent contact with the health care delivery system will allow women at risk to be identified and treated.

There are multiple depression screening tools available for use. These tools usually can be completed in less than 10 minutes. Most have a specificity ranging from 77% to 100%. Thus, it can be argued that sensitivity should be the determining factor to maximize the number of depressed patients identified. Many of these screening tools have been validated with specific ethnic populations. Examples of highly sensitive screening tools include the Edinburgh Postnatal Depression Scale, Postpartum Depression Screening Scale, and Patient Health Questionnaire-9 (see Additional Resources) (5). Other appropriate screening tools are listed in Table 1.

**Conclusion**

Depression is very common during pregnancy and the postpartum period. At this time there is insufficient evidence to support a firm recommendation for universal antepartum or postpartum screening. There are also insufficient data to recommend how often screening should be done. However, screening for depression has the potential to benefit a woman and her family and should be strongly considered. Women with a positive assessment require follow-up evaluation and treatment if indicated. Medical practices should have a referral process for identified cases. Women with current depression or a history of major depression warrant particularly close monitoring and evaluation.

**Coding**

Many payers require that evaluation and management services linked to mental health diagnoses be performed only by a psychiatrist or psychologist. Such payers typically cross-check the diagnosis submitted against the health care provider’s specialty. The appropriate diagnosis code will depend on the nature of the patient’s depression. Postpartum depression is assigned to code 648.4X (X is an indication that a fifth digit is required). However, if a code from the mental health chapter of the International Classification of Diseases, Ninth Revision, Clinical Modification (codes 290–319) is submitted by a health care provider whose specialty does not match their criteria, the claim is often denied. Medical practices should check with all payers concerning coverage for mental health services before billing for these services.
